Data Stories Planner

NAME _____ DATE _____

> Plan your data story on paper first. Then the loop is mostly copying from this page.

1. Get to know the data

Open `broadway.csv` and read the header row. Write each column's position. The first column is 0.

POSITION	COLUMN	WHAT IT HOLDS
_____	ShowType	Musical, Play, or Special
_____	Weeks	How many weeks it ran
_____	Performances	How many times it was performed
_____	TotalAttendance	Tickets sold, all weeks added up
_____	AvgCapacity	Percent of seats filled, on average
_____	TotalGross	Money taken in, in dollars

2. Pick your question

Choose one number column from the table. Not `Weeks`: that's the example.

My question: Do musicals or plays have a higher average _____?

I expect _____ to be higher, because _____

My chart: title _____ under the bars _____ up the side _____

3. Turn it into code

`kind` is the ShowType position, `col` is your column's. Spell `"Musical"` and `"Play"` like the file.

```
kind = ____
col = ____
musical_total = 0
musical_count = 0
play_total = 0
play_count = 0
for row in rows:
    fields = row.split(",")
    if fields[kind] == "_________":
        musical_total = musical_total + float(fields[____])
        musical_count = ____________________________
    if fields[kind] == "_________":
        play_total = _______________ + float(fields[____])
        play_count = ____________________________
musical_mean = _______________ / _______________
play_mean = _______________ / _______________
```

4. Test it

Rows counted (should be 850): _____ `musical_count + play_count` (should be 798): _____

My averages: musicals _____ plays _____ Was I right? _____
